13 **Abstract**

14 The objective of the study is to determine accumulation and translocation of heavy metals from  
15 soil to paddy straw irrigated with urban sewage wastewater in peri-urban region of Girudhumal  
16 sub basin area in Madurai. The soil samples were collected in seven locations irrigated with  
17 treated and untreated wastewater and analyzed for physical properties like pH, EC, bulk density,  
18 soil type, major (N,P,K) and micro nutrients (Fe, Mn, Cu, Zn) and heavy metals Ni, Cd, Pb. SEM  
19 analysis showed that soil structure is significantly influenced by waste water irrigation. It  
20 confirms that the waste water irrigation disturbs soil structure and affecting the plant growth in  
21 long run. Pb content was higher than the prescribed safe limits in S5 and S6 location, similarly  
22 Ni also was higher than the safe limit in all the locations. Pollution Load Index values are in the  
23 range of 0.08-0.56 for all sites, and it indicated that chance of heavy metal contamination is less.  
24 The EF values show moderate enrichment to Ni and Zn, Significant enrichment for Cd and Cu,  
25 Extremely high for Pb and deficiency for Mn. All these results confirmed that there is no  
26 immediate risk of heavy metal pollution, however with respect to Pb and Ni the plant tissues are  
27 showing higher values. The transfer factor for heavy metals from soil to paddy straw is less than  
28 0.5 for Cd and for others is more than 0.5 indicated greater chances for heavy metal

29 contamination.

30 **Keywords:** Heavy metals, Paddy Straw, Pollution Load Index, Enrichment Factor, Translocation  
31 Factor, SEM.

## 32 1. Introduction

33 Sustainable development of agriculture in India is restricted by a major factor of Water scarcity,  
34 since in India water is scarce due to the increasing growth in population, rapidly growing  
35 urbanization and industrialization, economic development. Severe water shortages are  
36 developing in many countries and water for agriculture is becoming increasingly scarce,  
37 particularly in India (Surendran *et al.*, 2014, 2016 and 2017). Access to adequate water for  
38 irrigation is a matter of concern in India, to meet demand for irrigation water for agriculture (i.e.  
39 more than 80 % of water use is for agriculture), non-conventional resources are used.

40 Availability and disposal of huge quantity of wastewater, due to the growth of industrial sector in  
41 India, is becoming a major problem, which makes the growing economies under pressure to sort  
42 it out (Minhas and Samra, 2004; Corcoran *et al.*, 2010). The technologies for treating  
43 wastewaters are often costly (Levy *et al.*, 2011), whereas the optimal use of wastewaters in  
44 agriculture for irrigation makes this as a low-cost alternative to treatment and helps in preventing  
45 uncontrolled dumping of wastewaters into water bodies (Drechel *et al.*, 2010). Nowadays, where  
46 ever water is scarce, wastewater is often used for irrigation / agricultural purpose. Review of  
47 literature showed that this was put into practice first in Melbourne, Australia, where sewage  
48 farms were established in 1897 (Shuval, 1990; WHO, 2006) and later being practiced in many  
49 countries such as New Zealand, China, India, Pakistan (Yang, Reichert and Abbaspour,2007;  
50 Minhas and Lal,2010)

51 Waste water irrigation (diluted or partially treated or raw), has both advantages and  
52 disadvantages. The benefits are conserving water and nutrients, reducing the pollution of water  
53 bodies, providing nutrients especially micronutrients and organic matter (FAO, 1992; Murtaza *et*  
54 *al.*, 2010; Hanjra *et al.*, 2012) and reliable irrigation resource in water scarce conditions which  
55 makes millions of urban and peri-urban farmers to depend on these waste water for their food  
56 security and livelihood options (Hoeks *et al.*, 2002; Qadir *et al.*, 2007).

57 On the other hand, the irrigation practices being primitive, unscientific and more of disposal  
58 oriented, these pose threat to farmer's/consumer's health and the environment through  
59 transmission of diseases from excreta related pathogens and vectors, skin irritants and  
60 irreversible accumulation of toxic chemical like heavy metals, pesticides etc. in soils and  
61 groundwater (Yadav *et al.*, 2002; Rattan *et al.*, 2005; Qadir *et al.*, 2007, 2010; Minhas and  
62 Lal, 2010; Murtaza *et al.*, 2010).

63 However, this wastewater-based irrigation has a number of limitations, includes the pollution of  
64 groundwater, built up of heavy metals, pesticides and other pollutants in the soil and the creation  
65 of habitat for harmful microorganisms which pose threat to farmer's/consumer's health and the  
66 environment through diseases from pathogens and vectors (Mapanda *et al.*, 2005; Murtaza *et al.*,  
67 2010; Qadir *et al.*, 2010 and Minhas *et al.*, 2015). Several studies confirmed the presence of  
68 heavy metals (Mogen Henze *et al.*, 2002; Cao and Hu, 2004; Mapanda *et al.*, 2005; Nan *et al.*,  
69 2002 ; Huang *et al.*, 2017; Yan *et al.*, 2018) ) and their potential bioaccumulation, when  
70 wastewater is used for irrigation. Papaioannou *et al.* 2015 proposed a method for accumulation  
71 of heavy metals by quantification and prediction of the pollution by way of elemental  
72 interactions i.e antagonistic or synergistic. Transfer of these heavy metals, from soil ecosystem  
73 to plant, depends on the heavy metal interaction in soil (Kalavrouziotis *et al.*, 2012). Heavy

74 Metals are highly toxic for plants phytotoxicity cause chlorosis, affects plant growth, variation of  
75 yields, reduced uptake nutrients and changes metabolism of plants (Broos *et al.*,2005; Qadir *et*  
76 *al.*, 2000). Wastewater mixed with river water used for crop irrigation for more than a decade,  
77 have caused metal accumulation viz Cd, Pb, Ni, Zn, Cr and Co into 31 % of soil surface  
78 (Assadian *et al.*, 1999). Transfer function (TF) calculation will suggest the interactions between  
79 these heavy metals in the soil and how they are getting transferred from soil to plants  
80 (Kalavrouziotis and Koukoulakis (2009) and Kalavrouziotis *et al.* (2012). These heavy metals  
81 enter the food chain and can result in a number of disorders to human health when concentrations  
82 exceed the safe limits (Martin and Griswold, 2009). The heavy metal toxicity affected the human  
83 populations by way of neurological disorders, central nervous system destruction, cancers of  
84 various body organs etc. to name a few (ATSDR, 1999). The authors have conducted studies for  
85 wastewater irrigated soil for heavy metal contamination. The alleviation policies to reduce heavy  
86 metal exposure through food are usually overlooked (Sharma *et al.*, 2014).

87 By keeping the above factors, it is most important to monitor soil health where wastewater  
88 irrigation being carried out in order to prevent the entry of heavy metals into food chain.  
89 Girudhumal river total length is 84 km, which flows in urban and peri urban stretch of Madurai  
90 for the first 24 km, carries urban sewage, solid waste, small scale industries wastes water ends  
91 with nearby peri urban irrigation tanks. Due to shortage of water for agriculture, this water is  
92 directly used for irrigation without prior treatment. Paddy crop (*Oryza Sativa*) is mainly  
93 cultivated on commercial scale using this untreated waste water for the past three decades around  
94 800 acres during rainy seasons. There is no information on heavy metals in soil and paddy crop  
95 in these areas. This study is aimed to assess the pollution indices and translocation of heavy

96 metals from soil to paddy straw and assessing the physical structure of the soil using Scanning  
97 Electron Microscope (SEM) analysis on the impacts of long term waste water irrigation.

## 98 **2. Materials and methods**

### 99 *2.1. Study area*

100 This study area selected was in the urban reach of Girudhumal river (with a length of 28 km) of  
101 Madurai city of Tamil Nadu, Southern part of India and situated at 9<sup>o</sup>25' N to 78<sup>o</sup>25' E as shown  
102 in Figure 1. It receives all the domestic sewage, solid waste, rice mill, bleaching and small-scale  
103 industries wastes in and around Madurai region. Moreover, the city drainage of Avaniyapuram  
104 Channel, Chinthamani Channel, Anuppanadi Channel, Panaiyur Channel and Sotathatti channel  
105 are joining into river. This river water is retained in large and small tanks and diverted to  
106 irrigation canals to be used by farmers for agricultural purposes and nearly 800 acres land get  
107 benefit for the past three decades. The predominant soil texture is clayey, loam and clay loam  
108 soils. This soil layers are in general fertile and suitable for growing many crops and paddy is the  
109 predominant crop in that area for both Rabi and Kharif period. The other crops cultivated are  
110 groundnut, banana, vegetables viz., Chilly and Greens. Urban and Peri urban reach of this area  
111 receives 806 mm of average annual rainfall, temperature varies from 15<sup>o</sup> to 41<sup>o</sup> C and relative  
112 humidity varies from 45 to 85 % and high in NE monsoon (Water Year, 2007).

### 113 *2.2. Soil sampling locations*

114 Seven sites were selected as shown in Figure 1 for collection of soil and paddy straw samples  
115 namely Thuvariman (9.9585<sup>o</sup>N, 78.0524<sup>o</sup>E)(S1) as controlled site irrigation with bore well water  
116 remaining six places are irrigated with treated and untreated wastewater namely Avaniyapuram  
117 (9.8771<sup>o</sup>N, 78.1137<sup>o</sup>E)(S2), Kaluvankulam (9.9252<sup>o</sup>N, 78.119<sup>o</sup>E)(S3), Chinthamani(9.892<sup>o</sup>N,

118 78.1413<sup>0</sup>E)(S4),Samanatham(9.866<sup>0</sup>N, 78.147<sup>0</sup>E)(S5), Sottathatti(9.8616<sup>0</sup>N, 78.1671<sup>0</sup>E)(S6) and  
119 Virathanoor (9.8142<sup>0</sup>N, 78.1771<sup>0</sup>E)(S7). Sampling in all the stations were taken in the year of  
120 October, 2015.

### 121 *2.3. Soil and paddy straw sample collection*

122 Soil and paddy straw samples were collected in October 2015 at the time of farmers harvested  
123 the crops. Straw from 10-20 paddy clumps were collected randomly from seven selected sites  
124 with same physiological age and identical size. All the samples were oven dried at 65<sup>0</sup> for 24  
125 hours and samples are dried, pulverized in wiley mill and stored in polythene bags for analysis.  
126 In order to analyze the influence of soil properties on agronomic performance, and to assess the  
127 impact of waste water irrigation, representative soil samples were taken from each field at post-  
128 harvest stage. Samples were taken from the cultivated soil layer (upper 20 cm), using a single  
129 auger and combining 12 samples evenly distributed over the field to one composite sample. The  
130 samples were air dried, crushed, and gravel and other particles of more than 2 mm were removed  
131 with a sieve. The samples were analysed in the soil laboratory, for the parameters listed below.

### 132 *2.4. Analytical procedures adopted*

133 The pH of soil was determined using Elico pH meter and EC was determined using a  
134 conductivity bridge (Jackson, 1973). The bulk density was determined by gravimetrically by  
135 Keen-Raczkowski brass cup. The Organic Carbon content of soil was estimated by chromic acid  
136 wet digestion method (Walkely and Black, 1934). The available Nitrogen by Macrojeldahl  
137 method (Piper, 1966), Phosphorus by Vandomolybdate method and Potassium by Flame  
138 photometric method in HCL extract (Stanford and English, 1949). For heavy metal extraction, 1g  
139 of dried sample of soil or paddy straw was digested in 15 ml of HNO<sub>3</sub>,H<sub>2</sub>SO<sub>4</sub> and HCLO<sub>4</sub>

140 mixture (5:1:1) at 80<sup>0</sup>C until a transparent solution was obtained (Allen *et al.*,1986). These  
 141 transparent solutions were then filtered through Whatman number 42 filter paper and diluted to  
 142 50 ml with distilled water. The concentration of heavy metal Ni, Cd, Pb, Cu, Fe, Zn of soil and  
 143 paddy straw samples were analyzed by atomic absorption spectroscopy (AAS, AA250-  
 144 VARIAN). The AAS value of blank (without sample) of each metal was deducted from the  
 145 sample value for final calculations (Singh *et al.*,2010). The characteristics of soil structure  
 146 analyzed by Phillips X2-30 Scanning Electronic Microscope (SEM) with a 3.5 nm of resolution.  
 147 Glass was properly cleaned and blank determination was used to correct the reading of  
 148 instruments. The results were found to be + or – 2 % of the certified values.

#### 149 2.5. Pollution load index (PLI)

150 To calculates the soil pollution severity, Pollution Load Index is used (Tomlison *et al.*,1980;  
 151 Harikumar *et al.*,2009) were derived the equation for PLI, is based on the concentration factors  
 152 of each metals. The PLI of the place are calculated by obtaining the n-root from the nCFs that  
 153 were obtained for all the metals which is given in equation 1 as follows,

154  $CF = C \text{ metal} / C \text{ background value,}$

$$155 \quad PLI = \sqrt[n]{CF_1 \times CF_2 \times CF_3 \times \dots \times CF_n} \text{----- (1)}$$

156

157 Where CF = Contamination Factor, n= no. of metals

158 C metal = Metal Concentration in Polluted Sediments.

159 C background Value = Background value of the metal

160 The PLI value >1 is polluted, whereas <1 indicates no pollution.

161 Turekian and Wedepohl (1961), were considered the World Average concentration of  
162 Cu(45 $\mu$ g/g), Ni(68  $\mu$ g/g), Mn (900 $\mu$ g/g), Pb(20 $\mu$ g/g) and Cd(0.3 $\mu$ g/g) reported as the  
163 background value.

#### 164 2.6. Enrichment factor

165 The Enrichment Factor (EF) was calculated to drive the degree of soil contamination and heavy  
166 metal accumulation in soil and in plants growing on contaminated site with respect to soil and  
167 plants growing on uncontaminated soil (Kisku, Barman and Bhargava, 2000). When  $EF < 2$  it may  
168 be deficiency to mineral enrichment,  $EF = 2-5$  it is moderate enrichment,  $EF = 5-20$  it is significant  
169 enrichment,  $EF = 20-40$  it is very high enrichment,  $EF > 40$  it is extremely high enrichment.

#### 170 2.7. Translocation factor

171 Translocation factor from soil to crop or mobilization ratio (Barman *et al.*,2000; Gupta *et*  
172 *al.*,2008 and Cui *et al.*,2004) was calculated to examine the relative translocation of metals from  
173 soil to other parts of the plants

### 174 3. Results and discussion

#### 175 3.1. Physico-chemical properties of soil

176 The soil texture was found to be generally clay loam soil. The soil pH values ranged from 7.93-  
177 8.8. The Control site S1 (Thuvariman, Bore water irrigation), have lower pH values than other  
178 wastewater irrigation sites (Table 1). The EC values ranges from 136-770 dS/cm and Organic  
179 Carbon (OC) values lies 0.42-.82% in all sites, lower values noticed in bore water irrigation site  
180 (S1) than wastewater irrigation areas (S2,S3,S4,S5,S6 and S7). Long-term sewage irrigation  
181 may cause can increase the OM content of irrigated soils. Similarly, EC values, sites S1,S3

182 (Kaluvankulam), and S7(Virathanoor) are the harmless to salinity effect and S2 (Avaniyapuram),  
183 S4(Chinthamani), S5(Samanatham) and S6 (Sottathatti) are have higher values cause salinity  
184 effect and limit to yield for crops. The surface soil was (0-20 cm) was richer in nutrients,  
185 availability of N,P,K in soils improved with sewage water irrigated sites, S6 have higher  
186 accumulated more nutrients than other sites. The N,P,K values ranges from 112-434 kg/ha, 22-  
187 150 kg/ha and 229-948 kg/ha respectively. The N values are <280 kg/ha for low values for all  
188 sites than S6 (Sottathatti) compared with standard limit values, P values > 22 kg/ha for all sites  
189 compared with standards and K for all sites >280 kg/ha higher in values than standards values. It  
190 is observed that P and K values are higher in all the sites, because of long time wastewater  
191 irrigation practices in all the sites. This was similar to the earlier reports of Jat *et al.*, (2016), in  
192 which they had the opinion that saving of nitrogen depend upon the accumulated organic carbon  
193 contents in soils as a result of sewage irrigation. However, in this study it is too early to decide  
194 that, farmers can go for skipping / reducing the quantity of fertilizers and we suggest to go in for  
195 fertilizers as recommended for normal water irrigated soils as recommended by agricultural  
196 universities. The micronutrients Fe, Mn, Zn and Cu had registered higher values in all the  
197 locations compared to control, except S7 location and ranges from 2.4-27.95 mg/kg, 0.22-16.57  
198 mg/kg, 0.42-19.14 mg/kg and 1.5-61.64 mg/kg respectively. This confirms that waste water  
199 irrigation increases the micronutrient levels in soils to sufficient level and which may induce  
200 toxicity in near future if continue to irrigate using untreated waste water.

### 201 3.2. Heavy metal concentration in soil

202 The concentration of heavy metals presents in the soil is given in Table 2. The control site  
203 S1(bore water irrigation and other sites S2, S3, S4, S5, S6 and S7 (Untreated and treated  
204 domestic sewage irrigation) mean concentration of heavy metals trends revealed that Cu(18.95)

205 is the dominant one followed by Mn(14.15), Ni(5.6), Zn(4.89), Pb(2.29), Cd(0.70). The present  
206 concentrations of metals for compared with permissible limits of Indian Standards (Awasthi,  
207 2000) and also international safe limits. However, the heavy metal present in control site is lower  
208 limit than other sites.

### 209 3.3. SEM analysis

210 The soil samples were scanned at various magnification modes to collect general information  
211 about morphological characteristics. From Figure 2, it is observed that, site S1 (Thuvariman) soil  
212 sample image, appear rather rough and the particles are well aggregated and finer (10  $\mu\text{m}$ ) grains  
213 are loosely aggregated on the surface. With respect to the site S2(Avaniyapuram) untreated  
214 wastewater irrigated soil, SEM image showed that the most of the material consists of grains  
215 greater than 10  $\mu\text{m}$  in diameter, coarse grains and are mostly of quartz (usually well-rounded), or  
216 more angular in shape. It also confirms that particles have porous and cracking structure. The  
217 site S3 (Kaluvankulam), irrigated with treated and untreated wastewater, the soil image from  
218 SEM analysis revealed that loose aggregate of fine grains and the surface of grains to be thickly  
219 coated in platy to poorly crystalline and the very bright grains with rough surfaces. The next site  
220 S4 (Chinthamani), using untreated wastewater for irrigation, SEM image showed that the soil  
221 samples are small, flaky or platy coatings on larger grains are probably clay. The loose  
222 aggregates of small grains are noticed in the surface. Many of the finer (<10  $\mu\text{m}$ ) grains are  
223 loosely aggregated into larger particles. In the case of S5 (Samanatham) using untreated  
224 wastewater for agriculture purposes, the SEM image illustrated that the flocculated arrangement  
225 of loosely packed grains. Shapes of soil particles were found to be angular with non-uniformed  
226 shapes. The surfaces were rough with sharp corners. Distribution of grain size of soil was within  
227 a range of 10 to 200  $\mu\text{m}$  with clearly defined porosity. SEM image of the site S6 (Sottathatti),

228 showed that the microstructure is more porous where pore spaces are relatively large. The  
229 surface of soil structure consists of thin plate like morphology. As shown in Figure 2, structure of  
230 soil consisted of many sheet-like particles. The flaky and plate-like particles could be identified  
231 as minerals. Soils that have flaky shape are likely to have high compressibility. The site S7  
232 (Virathanoor), SEM image illustrated that, the soil structure aggregates is clearly visible in the  
233 image. Those aggregates have three-dimensional structure are very different in shape, size,  
234 stability and interior structure. The aggregate structure has a strong influence on soil strength.  
235 This SEM image analysis clearly interprets the waste water irrigation continuously disturbs the  
236 soil structure. It confirms that fact that plants growing in structurally degraded soils are often  
237 constrained by water-logging and poor aeration when the soil is wet and by high strength, rather  
238 than by the availability of water, as the soil dries. Excessive contamination of these heavy metals  
239 may also have an adverse effect on soil structure, causing a decline in soil permeability, and  
240 therefore in a soil's ability to further accept and treat wastewater. Hence these soil properties  
241 need to be considered before applying the quantity of Waste water for irrigation.

#### 242 *3.4. Heavy metal concentrations in paddy straw*

243 The heavy metal concentrations for paddy straw are presented in Table 3. The concentration  
244 (mg/kg, dry wt.) of heavy metal in control site (S1) was found in the order of Zn  
245 (192)>Cu(54)>Mn(35)>Ni(1.52)>Pb(0.04)>Cd(0.01), whereas other sites heavy metal mean  
246 concentrations level was found in the order of Zn(154.29)> Cu(63.86) > Mn (49.43) > Ni (3.30)  
247 >Pb(1.71)>Cd(0.29) respectively. The Cd mean values for both soil (0.7 mg/kg) and paddy straw  
248 (0.29 mg/kg) respectively, there is no significance difference were found for both soil and paddy  
249 straw.

250 Irrigation through untreated waste water increased the concentration of heavy metals in paddy  
251 plants. The concentrations of all the heavy metals showed spatial variations, which may be  
252 ascribed to the variations in heavy metal sources and the quantity of heavy metals discharged  
253 through the sewage and effluents in irrigation water. Absorption and accumulation of heavy  
254 metals in plant tissue depend upon many factors, which include temperature, moisture, organic  
255 matter, pH, and nutrient availability. Soil properties influencing heavy metal availability varied  
256 significantly between the sites. In the case of S5 and S6, Pb content was higher than the  
257 prescribed safe limits, similarly Ni also was higher than the safe limit in all the locations. In the  
258 case of Cd it is well within the Indian standards in all the locations. The consumption of Ni and  
259 Pb contaminated portion of paddy by people / live stock may pose serious health hazards in long  
260 run (Sharma *et al.*, 2006, 2007). Interesting thing to observe is that the contamination levels were  
261 higher than permissible limits in the plant tissue, at the same sites where soil samples comply  
262 with established safe standards. Cd was easily absorbed by plants and transported to different  
263 parts of plants and no beneficial effects to plants (Jarvis, 1976). The Zn, Cu and Mn  
264 concentrations values were higher in paddy straw than in soil. These metals are required for  
265 various activities and plays important roles in growth of the plant and photosynthesis (Tripathi *et*  
266 *al.*, 1997). The heavy metals like Ni and Pb are required continuous monitoring and suitable  
267 measures are needed before these poses serious problems. Crop growth parameters and yield  
268 attributes are also significantly influenced by the waste water irrigation (Data not shown).  
269 Average yield obtained for Paddy from different sites are presented in Table 4. Data showed that  
270 the waste water irrigation significantly influenced the yield when compared to bore well  
271 irrigation water. Slight reduction in yield is due to the excess EC, Sodium content and alkaline  
272 pH, which might have influenced the uptake of other nutrients. Even though the waste water may

273 contain appreciable quantity of plant essential nutrients, organic carbon, the other factors such as  
274 Na, TDS, Heavy metals and EC needs to be taken care of, otherwise it will have a negative  
275 impact on the crop yield in the long run. Post harvest soils samples were analyzed for the impact  
276 of waste water irrigation. Salient results are discussed: Soil pH values vary from 7.1 to 9.4 in all  
277 these sites; EC values ranges from 0.2 to 2.1 dS/m; Organic Carbon varied from 0. to 1.8 % and  
278 as expected continuous irrigation had a significant effect over soil properties when compared  
279 with the fresh water irrigated area.

### 280 3.5. Pollution load index

281 The calculated PLI values varied from 0.08(S1)- 0.56(S6) and are presented in Figure 3. The  
282 lowest values was identified at control site (S1, Bore water irrigation) and higher values are  
283 observed at S6 (Sottathati) site, whereas untreated wastewater is used for irrigation, other values  
284 are S2 (0.1), S3(0.13), S4(0.17), S5(0.223) and S7(0.1) respectively.

### 285 3.6. Enrichment factor

286 The enrichment factor (EF) in all sites for heavy metals were found in the descending order of Pb  
287 (53.2) > Cu (10.64) > Cd (6.5) Zn (3.16) > Ni (3.16) > Mn (0.79) respectively and are presented in  
288 Table 5. Significant difference in EF values were observed among all the heavy metals. The  
289 values of EF was greater than 1, indicates that chances of accumulation of metals in plant species  
290 where wastewater used for irrigation (Kisku *et al.*, 2000). Among six metals estimated, the  
291 maximum EF was found to be Pb for soil Ni, Zn are moderate enrichment, Cd and Cu are  
292 significant enrichment, Mn is deficiency to mineral enrichment respectively.

### 293 3.7. Translocation factor

294 The ability of heavy metal species to transfer from the soil into plant roots is referred to as  
295 transfer factor (TF). The concentrations of metals in this study area were within the normal  
296 standards. The TF of the heavy metals from soil to paddy straw in the study area are presented in  
297 Figure 4. The TF values are in order from Zn(31.5) >Mn (3.49) >Cu (3.36) >Ni (0.653)  
298 >Pb(0.75)>Cd(0.40) respectively. The high toxic element concentrations indicate that some  
299 degree of heavy metal contamination occurred in the crops. According to study conducted by  
300 Sajjad et.al.,2009, if the transfer factor coefficient of heavy metal is greater than 0.50, the plant  
301 will have a greater chances of heavy metals contamination by anthropogenic activities. This  
302 indicates that the values of Ni, Pb and Cd concentrations of heavy metals in the plant are low but,  
303 there is a chance for it to be contaminated with Zn, Cu and Mn by further anthropogenic  
304 activities. In, world populations, most affected heavy metal toxicity are pregnant women and  
305 children (Boon and Soltanpour, 1992), central nervous system destruction, body organs cancers  
306 and disorders of neurological are some of the common report for heavy metal poisoning  
307 (ASTDR, 2000), hence enough mitigation measures need to be adopted in these areas.

308 In nutshell, the issue is that the contamination levels were higher than permissible limits in the  
309 plant tissue for some heavy metals at the site where even soil samples showed the value of heavy  
310 metals within the prescribed limits. **This study suggests that imperative consideration is required**  
311 **to focus on regular monitoring and pollution control mainly to ensure food for human**  
312 **consumption and regularize the use of sewage for irrigation.** This indicates, enough caution  
313 should be given to farmers for the use of waste water for irrigation. This has important  
314 implications for policy and programmes should be aimed at monitoring and controlling the level  
315 of heavy metal concentrations in irrigation water sources. Policies and programs need to be  
316 adapted so that local edaphic conditions and agricultural practices are taken into account, and

317 appropriate local measures developed for ameliorating heavy metal uptake by crops for a given  
318 set of local conditions. These measures need to be regularly reviewed to take into account factors  
319 such as the accumulation of heavy metals in the topsoil over time.

#### 320 **4. Conclusions**

321 In the present study, soil and plant samples were collected from peri-urban region of Girudhumal  
322 sub basin area in Madurai district, Tamil Nadu, India irrigated with urban sewage wastewater.  
323 The results showed that the value of pH for both soil and paddy straw are within the permissible  
324 limits. EC values for S1 and S7 are within permissible limit than other sites; possess salinity  
325 affect to soil and in long run will affect soil quality (soil fertility & structure) and limit the yield  
326 crops. The OC values are low in S1, medium in S2 site and high in other five sites, this may be  
327 due to use of long time wastewater irrigation. The nutrients values in all the sites showed that, N  
328 values are observed moderate in all sites, whereas P and K values are more than the permissible  
329 limit prescribed by Indian Standards. However, this accumulation of nutrients in the soil due to  
330 decades of untreated wastewater irrigation is a boon for agricultural production, since these  
331 nutrients are essential for plant growth, hence farmers can save money by reducing the quantity  
332 of P and K fertilizers. The micro nutrients Fe, Mn, Zn and Cu are also within standards limit.  
333 From the SEM images, it is observed that Control site (bore water irrigation) shows clear  
334 morphological characteristics of soil, particle are well graded and other wastewater irrigation  
335 sites shows soil particles are flaky and plate-like particles could be identified as minerals and the  
336 surface of grains to be thickly coated in platy to poorly crystalline. This structural deformation  
337 will result in poor growth of plants. The heavy metals Ni, Pb and Cd were assessed for both soil  
338 and paddy straw to determine the status of pollution load in the soil. The Pollution Load Index  
339 (PLI) values indicated that all the values are within 1, and there is a less chance of metal pollution

340 in the soil. The EF values for metals, Ni(3.16) and Zn(3.61) are shows moderate to enrichment,  
341 Cd (6.5) and Cu (10.64) shows significant enrichment, Pb(53.2) is extremely high and Mn(1.79)  
342 deficiency to mineral Enrichment. The transfer factor of heavy metals from soil to paddy straw  
343 are less than 0.5 for Cd, indicates less intake by the plant and other metals are greater than 0.5  
344 suggesting the possibility of heavy metal contamination. Long time wastewater irrigation more  
345 than decades impacts on soil quality and in turn may reduce value of land and periodic  
346 monitoring of soil quality levels are needed for effective irrigation management.

### 347 **Acknowledgements**

348 Authors profoundly thankful to laboratory facilities provided by Thiagarajar college of  
349 Engineering, Madurai, and Soil and Environment department, Tamil Nadu Agricultural  
350 University, Madurai for completion of this work. SEM analysis facilities offered by The  
351 Director, School of Civil Engineering, Karunya University, Coimbatore, Tamil Nadu  
352 acknowledged.

Kaluvankulam	S3	72	Paddy	Rabi	9000 <sup>b</sup>
Chinthamani	S4	32	Paddy	Rabi	8750 <sup>c</sup>
Samanatham	S5	72	Paddy, Banana	Rabi	9000 <sup>b</sup>
Sottathatti	S6	48	Paddy	Rabi	9000 <sup>b</sup>
Virathanoor	S7	71	Paddy	Rabi	8750 <sup>c</sup>

533 **Alphabets a to c indicates the significant difference at  $p < 0.01$**

534 **Table 5.** The Enrichment Factor for Heavy Metals in Soil

Metals	Enrichment Factors	
Ni	3.16	Moderate Enrichment
Cd	6.5	Significant Enrichment
Pb	53.2	Extremely high Enrichment
Zn	3.61	Moderate Enrichment
Cu	10.64	Significant Enrichment
Mn	1.79	Deficiency to mineral Enrichment
