13 **Graphical Abstract**

14

15 **Abstract:**

16 This research was conducted to investigate the possibility of producing compost from the residues of  
17 rapeseed, wheat, cucumber, and eggplant and evaluate the effect of biocompost produced and enriched  
18 with zinc and manganese on strawberry vegetative growth indices under drought stress. For this purpose,  
19 five treatments including one treatment with an equal mixture of produced biocomposts and four separate  
20 treatments of biocompost arisen from the residues of the studied plants enriched with zinc and manganese  
21 elements at a rate of 1 kg per square meter in all treatments under drought stress of 65% in a completely  
22 randomized design with three replications in greenhouse conditions were studied. The research results  
23 showed a significant difference at the levels of 1% and 5% in terms of vegetative growth indices  
24 including plant height, internode distance, fresh and dry weight of the plant, stalk diameter, and the  
25 number of strawberry tillers. In such a way that the highest amount of vegetative growth characteristics  
26 in strawberry bush was related to the treatment containing rapeseed-enriched biocompost under drought  
27 stress, and the lowest amount of them was related to the treatment containing an equal combination of  
28 biocompost from green cucumber, wheat, rapeseed, and eggplant. The analysis of variance results  
29 showed that the effect of biocomposts produced and enriched with elements of zinc and manganese under  
30 drought stress in treatments T1 (equal mixture of produced biocomposts) and T2 (biocompost produced  
31 from residues of wheat plant) and T5 (biocompost produced from residues of rapeseed plant) on  
32 strawberry vegetative growth indices was statistically significant. In such a way that the difference was  
33 observed at a level of 1% for all three aforesaid treatments in terms of plant height and the difference  
34 was observed at a level of 5 % for other vegetative characteristics (internode distance, fresh and dry  
35 weight of the plant, stalk diameter, and the number of tillers and fresh and dry weight of the root). The  
36 results indicated that the use of biocompost remain the positive effects on strawberry vegetative growth  
37 indices, and biocomposts produced individually (not combined) may be used under drought stress to  
38 improve the performance of strawberry vegetative growth.

## 40 **1. Introduction**

41 Compost, a processed mixture of organic materials, has long been of interest to farmers due to its unique  
42 and specific modifying effects on the physical, chemical, and biological properties of soil, as well as the  
43 improved growth and increased yield. The organic content of agricultural soils in Iran is mainly less than  
44 one percent. Therefore, as the use of mineral fertilizers may reduce soil quality in the long term, in recent  
45 years, sustainable production of agricultural products using organic fertilizers such as compost has had  
46 beneficial effects on plant growth and nutrient concentration in crops, leading to soil productivity and  
47 health preservation (Hamdpour Sefidkoochi et al. 2012). Findings of a research conducted by Pergola et  
48 al. (2018) demonstrated a significant positive impact of compost application on growth parameters such  
49 as plant height, number of tillers, spike length, straw yield and thousand-grain weight. Aynehband et al.  
50 (2023) compared the production of compost fertilizer from the residues of rice, rapeseed, and wheat  
51 crops, as well as sugar beet, and its effect on the grain yield and some agronomic characteristics of wheat.  
52 They found that the highest grain yield of wheat and also the highest protein content of the grain were  
53 obtained under the application of compost produced from rice residues with a weight percentage of 20%.  
54 Therefore, from an agroecological perspective, it was determined that in order to reduce the use of  
55 chemical fertilizers and replace them with compost, attention to the quantity, quality, and type of raw  
56 material in compost production will be essential.

57 Additionally, using natural substances such as organic fertilizers in the soil is one of the solutions to  
58 reduce the impact of drought stress on crops (Namarvari et al. 2013), which leads to an increase in water  
59 holding capacity of the soil, enhancement of organic substances and pH balance in the soil, improvement  
60 of cation exchange capacity, provision of essential plant nutrients such as nitrogen, soil structure  
61 amendment, increase in microorganism activity, creation of a suitable environment for root growth,

62 increase in photosynthesis, aerial organ growth, dry matter production, and ultimately plant performance  
63 improvement. Additionally, these substances create less pollution in the environment compared to  
64 chemical fertilizers (Sajadink et al. 2011). In a study examining the effects of different organic fertilizers  
65 and arbuscular mycorrhizal fungi on the performance and yield components of wheat varieties, it was  
66 reported that the highest spike length, thousand-grain weight, grain yield, biological yield, and wheat  
67 harvest index were obtained in the treatment using vermicompost fertilizer + arbuscular mycorrhizal  
68 fungi (Gholamalizade Ahangar et al. 2014). Some studies have shown that in plants exposed to drought  
69 stress, the use of compost fertilizer increases plant tolerance to drought stress and enhances plant  
70 performance (Safi et al. 2022). In a study evaluating the effects of water cut stress and the application of  
71 compost fertilizer on the performance and yield components of the cranberry bean, it was observed that  
72 drought stress led to a decrease in performance and yield components. However, the application of 10  
73 tons per hectare of compost fertilizer resulted in an increase in these characteristics (Najarian et al. 2016).  
74 In another study, the effects of vermicompost fertilizer and chemical fertilizer on the performance and  
75 yield components of chickpea varieties under drought stress were studied and it was reported that under  
76 drought stress in the pod filling stage, the number of grains per pod, thousand-grain weight, grain yield,  
77 biological yield, and harvest index were obtained in the treatment using 50% chemical fertilizer + 50%  
78 vermicompost (Kahrizi and Sepehri 2019). Pandiyana et al. (2020) stated that the characteristics of  
79 vermicompost, in addition to being rich in elements and some growth-stimulating enzymes, gradually  
80 release nutrients, leading to an increase in phosphorus and nitrogen levels in the soil, a decrease in soil  
81 bulk density, and an improvement in soil water holding capacity. These conditions improved the plant  
82 height, the number of branches, root length, as well as the number and weight of the capsules in the  
83 sesame plant, so that the application of 10 to 30 tons per hectare vermicompost improved the weight of  
84 sesame capsules by 25 to 50% on average. Mahmoudi et al. (2020) demonstrated that the combined

85 application of vermicompost, nitrogen, and phosphorus fertilizers had the highest impact on the  
86 morphological characteristics of peppermint (*Mentha piperita L.*) such as plant height and node number,  
87 as well as the highest quantity and quality of essence (including alpha-pinene, limonene, isomenthone,  
88 menthol, 1,8-cineole, and menthone). The beneficial impact of biofertilizers has been proven in various  
89 studies, including on plants such as garden sage (Yadegari 2018) and saffron (Omidi et al. 2009).  
90 Moradi and Sheikhi (2020), in their study on the effect of mycorrhizal fungi and vermicompost on the  
91 growth and composition of mineral elements of strawberry cultivars demonstrated that the use of organic  
92 fertilizers increased the growth of strawberry plant by increasing in absorption of nutrients, which  
93 vermicompost played a more prominent role due to its nutrient content and beneficial soil organisms.  
94 In another study, Ghaem Maghami et al. (2020) examined the effects of different levels of nitrogen,  
95 vermicompost, and nitrazine on the morphological characteristics, chlorophyll index, and strawberry  
96 yield in greenhouse conditions and the results showed that the growth and performance of strawberry  
97 with the application of 75 kilograms per hectare of nitrogen along with nitrazine and vermicompost were  
98 similar to those with the application of 100 kilograms of nitrogen alone. Therefore, the use of organic  
99 fertilizers can not only improve plant performance, but also reduce the consumption of chemical  
100 fertilizers up to 25%. Also, the research results of Arancon et al. (2004) showed that the use of  
101 vermicompost increases the dry weight of strawberry. Khaleeq and Shokohian (2018) in a study  
102 investigating the effect of vermicompost extract (compost tea) on the growth and yield of strawberry  
103 showed that the effect of different treatments of compost tea on all the measured characteristics were  
104 statistically significant at the probability level of 1%. Given the use of biocompost arisen from plant  
105 residues, disposal of which causes pollution in the environment, may optimally improve the vegetative  
106 growth and reproductive performance of agricultural products in agricultural fields and greenhouses and  
107 reduce drought stress (Abyar et al. 2016). Therefore, this study aims to investigate the possibility of

108 producing and comparing the quality of compost produced from residues of different plants, as well as  
109 to evaluate its effect on strawberry vegetative growth indices.

## 110 2. Methodology

111 This experiment was conducted in two stages in the summer of the year 2021 at a greenhouse site in  
112 Jiroft city in Kerman province. Jiroft city, due to locating in the southern latitudes of Iran and medium  
113 height, is spread out in a wide valley and enjoys a plain and mountainous locations, which bears hot and  
114 relatively humid summers and mild and short winters; So that the days with a temperature of 0 °C or less  
115 during the cold season may not exceed one week.

116 The first stage of the experiment including production of compost fertilizer from plant residues, was  
117 carried out using windrow compost production method. The studied treatments were made up of  
118 greenhouse residues of cucumber and agricultural residues of wheat, eggplant and rapeseed crops. The  
119 moisture percentage of plant residues ranged from 10 % to 15% on average. Animal (sheep) manure was  
120 used as the initial substrate to prepare compost. The chemical characteristics of plant residues are  
121 presented in table 1. Before compost production and after compost processing, pH parameters,  
122 percentage of organic carbon as well as percentage of total nitrogen, phosphorus, potassium, low  
123 consumption elements such as iron, manganese and zinc were measured and C/N ratio was calculated.  
124 During the compost production process, urea fertilizer was used to adjust the C/N ratio. Also, the amounts  
125 of humidity, temperature, and pH were measured and controlled every 15 days to supervise the  
126 production process.

127 **Table 1-** Average values of the physicochemical characteristics of the initial substrates before starting  
128 production of compost from residues of wheat, eggplant, cucumber and rapeseed.

| Type of plant residues | C/N   | % (N) | (P)%  | % K <sub>2</sub> O | (Fe)<br>mg/kg | (Mn)<br>mg/kg | (Zn)<br>mg/kg | pH   |
|------------------------|-------|-------|-------|--------------------|---------------|---------------|---------------|------|
| Wheat                  | 19.42 | 1.13  | 1.15  | 1.16               | 7124          | 394           | 142           | 7.97 |
| Eggplant               | 17.10 | 1.54  | 1.27  | 1.69               | 7346          | 519           | 149           | 7.91 |
| Cucumber               | 18.61 | 1.47  | 1.35  | 1.93               | 7249          | 476           | 140           | 7.92 |
| Rapeseed               | 18.04 | 1.72  | 1.89  | 1.74               | 8136          | 593           | 157           | 7.90 |
| Animal manure          | 33.24 | 1.65  | 1.003 | 1.29               | 8153          | 234           | 69.7          | 7.82 |

129 During compost processing, the temperature ranged from 37 °C to 60 °C and also, the piles were  
130 manually turned upside down twice a week for proper aerobic decomposition. Irrigation and aeration of  
131 experimental substrates were performed two to three times a week for four months. After the end of the  
132 test period and production of compost fertilizer, it was passed through a 3.5 mm sieve (Lataverma and  
133 Marshner, 2013) and then weighed. The moisture content of air-dried fertilizer samples was about 15%.  
134 The produced composts were sampled and then, values of phosphorus were measured by vanadate  
135 molybdate method through a spectrophotometer at a wavelength of 470 nm (Emami, 1996). Meanwhile,  
136 nitrogen was measured by Kjeldal method, potassium and calcium by flame photometer, as well as micro  
137 elements (zinc, manganese, iron) by atomic absorption device.

138 **Table 2-** Average values of physicochemical properties of initial substrates in the first and final stages  
139 of compost production from wheat, eggplant, cucumber, and Rapeseed residues

| Type of compost produced from plant residues | Compost from production stages | C/N   | (N) % | (P)% | K <sub>2</sub> O % | (Fe)<br>mg/kg | (Mn)<br>mg/kg | (Zn)<br>mg/kg | pH   |
|--|--------------------------------|-------|-------|------|--------------------|---------------|---------------|---------------|------|
| Wheat  | First stage                    | 24.32 | 0.69  | 0.36 | 0.43               | 5349          | 184           | 89            | 6.91 |
|  | Final stage                    | 19.42 | 1.16  | 1.19 | 1.18               | 7264          | 398           | 146           | 7.86 |
| Eggplant                                     | First stage                    | 10.2  | 0.93  | 0.58 | 0.73               | 5149          | 217           | 92            | 6.93 |
|  | Final stage                    | 17.23 | 1.58  | 1.29 | 1.75               | 7469          | 523           | 151           | 7.89 |
| Cucumber                                     | First stage                    | 13.29 | 0.96  | 0.74 | 0.85               | 5132          | 192           | 83            | 6.84 |

|          |             |       |      |      |      |      |     |     |      |
|----------|-------------|-------|------|------|------|------|-----|-----|------|
|          | Final stage | 18.67 | 1.68 | 1.39 | 1.95 | 7389 | 481 | 147 | 7.94 |
| Rapeseed | First stage | 12.21 | 0.98 | 0.83 | 0.78 | 6123 | 318 | 102 | 6.92 |
|          | Final stage | 18.15 | 1.76 | 1.93 | 1.76 | 8167 | 601 | 162 | 7.91 |

140 The second stage consisted of investigating the effect of different types of compost fertilizers produced  
 141 from residues of cucumber, eggplant, wheat and Rapeseed plants as well as adding urea fertilizer,  
 142 manganese and iron (each at a rate of 1 kg per one square meter of substrate) and applying drought stress  
 143 on strawberry vegetative growth performance. This experiment was conducted as a factorial experiment  
 144 in a completely randomized design (CRD) with 5 treatments in 3 replications under drought stress of  
 145 65% by weight of field moisture. Five treatments were used as follows:

- 146 • Treatment 1 (drought stress and equal composition of biocompost produced from green cucumber,  
 147 wheat, rapeseed, eggplant at a rate of 1 kg per square meter),
- 148 • Treatment 2 (drought stress and wheat biocompost enriched with zinc and manganese at a rate of 1  
 149 kg per square meter),
- 150 • Treatment 3 (drought stress and green cucumber biocompost enriched with zinc and manganese at a  
 151 rate of 1 kg per square meter),
- 152 • Treatment 4 (drought stress and eggplant biocompost enriched with zinc and manganese at a rate  
 153 of 1 kg per square meter)
- 154 • Treatment 5 (drought stress and rapeseed biocompost enriched with zinc and manganese at a rate of  
 155 1 kg per square meter).

156 The studied and cultivated plant was Paros variety strawberry. After preparing the greenhouse land, some  
 157 plots with dimensions of 2 m × 2 m were created and covered with black plastic mulch afterward. In  
 158 early November, 100 bushes were cultivated in each plot and they were harvested once. The fruit yield  
 159 was measured at the time of harvesting in January and February, and fresh and dry weights of the plant

160 at the end of February. The measured indices in this research included vegetative growth components  
 161 such as, plant height, internode distance, fresh weight of the plant, dry weight of the plant, number of  
 162 tillers, stalk diameter as well as fresh and dry weight of the root. Vegetative growth characteristics were  
 163 measured after removing the margins in each plot. The fresh weights of leaves and roots were measured  
 164 immediately after transfer from the greenhouse to the laboratory through a digital scale with an accuracy  
 165 of 0.01 grams. The samples were placed in paper pockets and then were dried in an oven at a temperature  
 166 of 80 °C for 72 hours, next, the dry weight of the samples was measured using a scale (Tabatabaei 2013).  
 167 SAS software was used for statistical calculations and data variance analysis. Meanwhile, comparison of  
 168 averages was carried out with Duncan's multiple range test at a level of 5 %.

### 169 3. Results and Discussion

170 This study investigated the possibility of producing compost from residues of cucumber, wheat, eggplant,  
 171 and rapeseed remained in the agricultural fields and greenhouses and evaluated its effect on strawberry  
 172 vegetative growth indices under drought stress, considering the nutrients such as zinc and manganese.  
 173 The physicochemical characteristics of the produced compost are tabulated in Table 3.

174 **Table 3-** Average values of the physicochemical properties of compost produced from wheat, eggplant,  
 175 cucumber, and rapeseed residues.

| Type of treatment<br>Parameter | Wheat                    | Eggplant                  | Cucumber                 | Rapeseed                 |

176 Sd: Standard deviation is obtained from the average of repetitions related to each treatment.

177 After producing biocompost from residues of wheat, cucumber, eggplant and rapeseed, these  
 178 biocomposts enriched with zinc and manganese elements were added separately to each plot in 5  
 179 treatments in a rate of one kilogram per square meter under drought stress. Then strawberry plants were  
 180 planted in these plots so that the effect of these biocomposts on strawberry vegetative growth may be  
 181 measured. The analysis of variance results for the effects of different treatments on strawberry vegetative  
 182 growth indices are demonstrated in Table 4.

183 **Table 4-** Analysis of variance of the effect of biocompost produced from rapeseed, eggplant, cucumber  
 184 and wheat enriched with zinc and manganese on strawberry vegetative growth indices under drought  
 185 stress (source: research findings)

186 (\*\*) Significance was achieved at the 1% level, (\*) significance was achieved at the 5% level, (ns) significance was not  
 187 achieved.

188 The analysis of variance results showed that the effect of biocomposts produced and enriched with  
 189 elements of zinc and manganese under drought stress in treatments T1 (drought stress and equal mixture  
 190 of biocomposts produced from residues of green cucumber, wheat, rapeseed and eggplant) and T2  
 191 (biocompost produced from residues of wheat plant) and T5 (biocompost produced from residues of  
 192 rapeseed plant) on strawberry vegetative growth indices was statistically significant. In such a way that  
 193 the difference was observed at a level of 1% (confidence level of 99 %) for all three aforesaid treatments  
 194 in terms of plant height and the difference was observed at a level of 5 % (confidence level of 99 %) for  
 195 other vegetative characteristics (internode distance, fresh and dry weight of the plant, stalk diameter, and  
 196 the number of tillers and fresh and dry weight of the root) (table 4). The average comparison results of  
 197 vegetative growth characteristics for the studied plant are presented in Table 5.

198 **Table 5- Comparison of the average effect of biocompost produced from rapeseed, eggplant,**  
 199 **cucumber and wheat enriched with zinc and manganese on growth indices of strawberry under**

201 Sd: Standard deviation is obtained from the average of repetitions related to each treatment.

202 - In each treatment, the highest value is indicated by the letter “a” and the lowest value by the letter “d”.

203

204 The average comparison results of the treatments showed that the highest amount of strawberry  
205 vegetative growth components was in rapeseed biocompost treatment (treatment 5) followed by  
206 treatments 4 and 3 (biocompost produced from residues of eggplant and cucumber) as well as treatment  
207 2 (biocompost produced from residues of wheat), respectively. The lowest amount was obtained in  
208 treatment 1 (drought stress and equal composition of biocompost produced from residues of green  
209 cucumber, wheat, rapeseed and eggplant) (Table 4). Although there was no statistically significant  
210 difference in the characteristics studied in two treatments T3 (biocompost produced from residues of  
211 eggplant) and T4 (biocompost produced from residues of cucumber), the values of the measured  
212 agricultural characteristics were high and close to each other. In such a way that the measured values of  
213 vegetative growth characteristics in these two treatments were at the level “b” of the treatments’ average.

214 The comparison of different treatments showed that the effect of biocomposts in an unmixed form and  
215 alone had more effects on vegetative growth components, which was caused by the difference in the  
216 amounts of macro and micro elements in the produced biocomposts (Table 2). In such a way that the  
217 lowest vegetative growth was observed in the biocomposts’ mixture treatment, because the obtained  
218 composition could not provide the appropriate amount of growth essential elements in this biocompost.  
219 Therefore, it can be stated that the use of biocomposts bearing high amounts of micro and macro elements  
220 is able to increase strawberry vegetative growth indicators. Mafakheri et al. (2011) stated that the use of  
221 vermicompost at a level of 1%, due to having high percentage of nitrogen, had a significant effect on the  
222 leave greenness index of *Dracocephalum Moldavica*. Fernandez et al. (2010), in an experiment conducted  
223 on beans, showed that the addition of 8.2 of the weight percent of vermicompost had the greatest  
224 contribution in increase of leave greenness index of beans due to having high percentage of nitrogen.  
225 Because such leaves are not able to consume the light and convert the light energy into the energy needed

226 by the plant during the process of photosynthesis (Theunissen et al. 2010) as well as, chlorophyll is the  
227 main pigment for light absorption and photosynthesis in plants, in which food elements are involved in  
228 its structure (Wang and Chen 2023). Therefore, nutrients such as nitrogen, phosphorus, potassium, iron  
229 and copper are easily available to plants through application of vermicompost and are used in the  
230 formation of chlorophyll, which is needed to collect light and convert it into chemical energy (Zhao et  
231 al. 2022).

232 The results showed that the highest amount of vegetative growth indicators was related to rapeseed  
233 biocompost treatment. The reason can be due to the high amount of macro elements (nitrogen,  
234 phosphorus, potassium) and micro elements (iron, manganese and zinc) in this treatment compared to  
235 other treatments (Table 3). Ghaem Maghami et al. (2020) and Mirshekari et al. (15) also announced that  
236 the high level of macro elements through biofertilizers resulted in the highest greenness index in corn  
237 and strawberry plants. In addition, the results of a research conducted by Pour Moghaddas and  
238 Zafarzadeh (2016) also showed that the combination of biocompost with animal and chemical fertilizers  
239 causes better performance of strawberry plant. The analysis of variance results and comparison of data  
240 average in different treatments showed that the effect of different biocompost treatments obtained from  
241 different plant residues on dry weight of strawberry aerial organ was significant. In such a way that the  
242 highest dry weight of aerial organs by 14.2 grams per plant was related to rapeseed biocompost treatment  
243 and the lowest amount by 11.61 grams per plant was related to the mixed biocomposts treatment obtained  
244 from residues of rapeseed, cucumber, eggplant and wheat. As mentioned above, this difference in plant  
245 dry weight may be caused by the high amount of macro elements in the biocompost of the treatments, so  
246 that the highest amount of nitrogen by 1.99% was related to the rapeseed treatment and the lowest amount  
247 by 1.37% was related to the wheat biocompost treatment. On the other hand, the highest amounts of  
248 phosphorus and potassium elements were related to rapeseed biocompost by 2.03% and 2.4%,

249 respectively, while the lowest amounts of this elements belonged to wheat biocompost by 1.32% and  
250 1.44%, respectively.

251 When enough nitrogen is available to the plant, the need for other principal nutrients such as phosphorus  
252 and potassium increases. This element accelerates the growth. Therefore, nitrogen influences all the  
253 characteristics affecting the performance and biological performance (Sajjadi et al. 2011). Also, Ghaem  
254 Maghami et al. (2020) showed that the highest dry weight of aerial organ was obtained with application  
255 of nitrogen in a rate of 100 kg/ha, 1% vermicompost inoculated with nitrazine in strawberry plants in  
256 greenhouse conditions. They stated that the use of biological fertilizers can reduce the use of chemical  
257 fertilizers by 25% while increasing plant yield. Moradi and Sheikhi (2020) also achieved the conclusion  
258 that the use of biological fertilizers increases the growth of strawberry plants by increasing the absorption  
259 of nutrients. Wang and Lin (2002) showed that the use of compost mixed with soil significantly increased  
260 dry weight of aerial organs of strawberry cultivars. Arancon et al. (2004) stated that the use of  
261 vermicompost significantly increased the growth and yield of strawberry. The results of the present study  
262 are in line with the results of the study conducted by Abyar et al. (2017), who investigated the effects of  
263 drought stress and macro elements of zinc and manganese on the morphological characteristics and  
264 performance of common millet (*Panicum Miliaceum*) plant. The results of both studies showed that under  
265 drought stress, the use of micro elements of zinc and manganese increases vegetative growth  
266 characteristics and finally plant yield. Also, the results of the present study are consistent with the results  
267 of a research conducted by Terry et al. (2020) on the effect of micro elements of zinc and manganese as  
268 well as vermicompost produced from plant residues on strawberry yield and vegetative growth  
269 characteristics under drought stress. The results of this research indicate that drought stress can affect the  
270 quantitative and qualitative performance of strawberry without having a significant negative effect on  
271 fruit weight and having a significant positive effect.

272 In the study on the effect of biocompost on fresh and dry weight of roots, Armand et al. (2015) and Pant  
273 et al. (2012) reported that by increasing levels of vermicompost and compost tea in the soil, root  
274 characteristics such as length, fresh weight and dry weight were enlarged. In the present study, the effect  
275 of biocompost on the number of tillers and fresh and dry weight of strawberry roots was significant. In  
276 such a way that the highest dry and wet weight of strawberry roots by 46.14 gram and 14.97 grams per  
277 plant, respectively, were related to rapeseed biocompost treatment, and the lowest ones by 43.11 gram  
278 and 14.02 grams per plant, respectively, were related to the treatment with an equal composition of  
279 produced biocomposts. The results showed that under drought stress and water reduction, application of  
280 biocompost obtained from the residues of rapeseed enriched with zinc and manganese elements was able  
281 to overcome the negative effects of the applied stress and acquire the highest strawberry vegetative  
282 growth components. The high level of vegetative growth indicators in the rapeseed biocompost treatment  
283 can be related to increase in supply and absorption of nutrients through reduction of soil pH and nitrogen  
284 fixation and production of hormones increasing strawberry growth (Das et al. 2008; Juan et al. 2018). In  
285 such a way that the lowest pH value was related to rapeseed biocompost by 6.44 and the highest value  
286 was related to cucumber biocompost by 7.53.

#### 287 **4. Conclusion**

288 The superficial root system, large leaf surface and high-water content of strawberry fruits cause the  
289 consumption of large amounts of water. Strawberry plant is very sensitive to drought stress during  
290 flowering and fruit ripening. In this research, biocompost was produced from residues of rapeseed,  
291 eggplant, cucumber and wheat, then, each of these biocomposts produced in different treatments were  
292 mixed with zinc and manganese elements and evaluated and measured under drought stress for the effect  
293 on strawberry vegetative growth indicators. As per the results observed in the experiment, it was  
294 determined that the biocompost produced from residues of rapeseed enriched with zinc and manganese

295 elements, led to better growth of the plant vegetative indicators than other treatments. In such a way that  
296 under drought stress, this treatment showed a better result and increased the tolerance of the plant to  
297 drought stress and made the plant performance better. In general, as per the results obtained from the  
298 strawberry plant, the use of each biocompost produced from residues of rapeseed, eggplant, cucumber,  
299 and wheat enriched with zinc and manganese elements can alone lead to proper growth of vegetative  
300 growth indices and performance of strawberry plant under drought stress than mixing equal proportions  
301 of these biocomposts.

## 302 **5. Acknowledgments**

303 This article has been adapted from the Ph.D. dissertation (No3520488648985567403162458759) in  
304 environmental science and engineering by Marzieh Faizipour at Islamic Azad University, Damavand  
305 Branch, Iran. The authors would like to express their gratitude for the support of this university in  
306 implementing the current project.

## 307 **6. Data availability statement**

308 The authors confirm that the data supporting the findings of this study are available in the article and its  
309 supplementary materials as PhD Thesis at Islamic Azad University of Damavand Branch, Iran
