7 Abstract

3

8 This study describes a simple way for making films from natural sources, which is relevant since there is a rising demand for new materials that can make biocompatible films that are both 9 10 effective and economical for use in biomedical applications. Fish bone waste and chitosan, a natural polymer used to manufacture thin films, are the sources of hydroxyapatites. The addition 11 of zirconia (ZrO₂) to the thin films created a new nanocomposite known as ZrO₂-Chitosan-12 Hydroxyapatite (Zr-CS-HAP) films. These films demonstrated biocompatibility and have the 13 potential to be produced in huge quantities. The structural, morphological, and biological studies 14 were explored for possible biomedical applications like wound dressing, bone tissue 15 regeneration, etc. The films showed good anti-oxidant and UV-protecting properties. 16 Cytotoxicity of films by MTT test suggests that HeLa cell lines showed moderate to good 17 cytotoxicity and better cervical properties. The films tested for Apoptosis-Necrosis in HeLa cells 18 showed induced apoptosis of 52% and Necrosis of 21.3% in HeLa cells, similar to standard 19 20 control.

29 1 Introduction

Bioceramic materials used for knee, femur, hip, teeth, and other biological implants are designed 30 to be highly absorbent and, in addition to their adequate load-bearing ability, can encourage the 31 formation of natural bone tissue on the surfaces of artificial joints (Mythili et al. 2015). The 32 33 creation of hybrid biomaterials with antibacterial, antifungal, anti-proliferative, and antioxidant capabilities is crucial for promoting quicker and more effective healing. In order to achieve 34 35 superior orthopedic outcomes, an implant material must be mechanically and biologically sound and pass a corrosion-resistant test (Cunha et al. 2020). Metallic bio implant materials are 36 essential in clinical applications because of their better mechanical qualities in physiological 37 conditions. Hydroxyapatite [Ca₁₀[PO₄]₆[OH]₂], a calcium /phosphate-based bio-ceramic (Komal 38 39 et al. 2020) chemically like an inorganic constituent of bone tissue, and is non inflammatory, non immunogenic, biocompatible but also bioactive, has the ability to form a direct bond with living 40 tissue (Fathi et al. 2008). It promotes tissue growth and is used as a prosthetic implant and filler 41 material to replace damaged bones. Hydroxyapatite is promising for bone therapy, bone 42 43 replacement, bone repair material, and wound dressing material (Rinaudo, 2006). Although HAP has a significant potential for wound healing because to its high biocompatibility and excellent 44 angiogenic activity, traditional HAP materials are not suitable for wound dressing due to their 45 high brittleness and poor mechanical qualities. However, the ability to add different dopants or 46 reinforcements to HAP improves its qualities and expands its applications (Lansdown, 2002). 47 Zirconium dioxide (ZrO₂) is a widely used material due to its excellent properties like 48 biocompatibility, excellent mechanical strength, elastic modulus equivalent to that of bones, low 49 stress, and high fracture toughness (Horti et al. 2020). Zirconia-based composite materials have 50 superior corrosion resistance, high hardness, fracture toughness, and less magnetic susceptibility, 51 making them useful for a variety of biomedical applications. One of the major components used 52 in biomedicine is chitosan (CS), obtained by deacetylation from chitin, a natural polysaccharide 53 54 found in crustacean shells. Chitosan has many biological properties, such as antibacterial, nontoxic, and biodegradable. The degree of deacetylation (DDA) has a considerable impact on 55 the solubility of chitosan. Chitosan is soluble up to a pH of 9 when its DDA is less than 40%. 56 57 The Development and characterization of chitosan films were done to study the morphology and physical, mechanical, and degradation properties (Yang et al. 2010). 58

59 2 Methodology

Local market fish bones are defatted and deproteinized. Crushed bone species cleaned after 2 60 hours in acetone and heated to 250°C for six hours while stirring in a highly concentrated 4N 61 sodium hydroxide solution with a 1:40 solid/liquid weight ratio. 20 g of bone powder in a 62 crucible is heated at 650°C @ 5°C for 6 h and 950°C for 6 hours (Barakat et al. 2008). A beaker 63 with 1M ammonium hydroxide contained the estimated amounts of ZrOCl₂, a precursor to ZrO₂, 64 and bone powder to maintain pH 8. At 65–70°C, the mixture is stirred often. After washing and 65 drying overnight at 45° C, the solid is calcined at 700° C for an hour. With vigorous stirring, 66 Glacial acetic acid [1%v/v] dissolved chitosan at 25°C in 24 hours. Zr-HAP powder was added 67 in various amounts after dissolving. A 0.5 N NaOH solution and distilled water rinse neutralized 68 excess acetic acid. For film preparation, plasticizer glycerol was added and agitated at 40° C for 69 30 minutes to 60 mL. Glycerol as a plasticizer is added and swirled at 40° C for 30 minutes by 70 eliminating air bubbles and particles to make the film. The solution was cast and evaporated onto 71 a glass plate and dried for 72 h at 25 °C to form the film after 10 min of stirring at 40° C (Iline et 72

al. 2022). Zr concentrations and weight percents are in Table 1. The prepared films were
characterized with XRD, SEM, FTIR (Srinivasan *et al.* 2018). A calibrated digital Vernier
Calliper-gauge micrometer measures film thickness. Five locations are measured and averaged
for each film. Film microstructure and quality may change with doping (Gao, 2004). Porosity
was measured using a standard approach (Khorasani *et al.* 2019). Each film was weighed before
and after 60 minutes in dry ethanol until saturated.

80 Table 1 Details of the weight percentages of the components used in the preparation of the film

81

To assess swelling and water-uptake (WU%), 25 × 25 mm films were submerged in 5 mL of saline solution (NaCl 0.9% w/v) adjusted to pH 6.6. WU at 120 minutes was calculated using weight differential %. Hydrated samples were submerged in solution and baked at 60 °C for 24 hours to quantify erosion by weight. Erosion (E%) measures film weight loss in saline. For 24 h at 37 °C, the films were immersed in saline solution to measure disintegration and integrity.

87 Biological assessment

88 Human Cervix adenocarcinoma cell line HeLa is supplied from NCCS in Pune, India for film cytotoxicity. At 37°C with 5% CO₂ and 18–20% O₂, the cells were in DMEM with high glucose 89 media, 10% FBS, and 1% antibiotic-antimycotic solution in a CO₂ incubator. Their subculture 90 changed every two days. Colorimetric MTT cell proliferation assay used to measure cell 91 92 proliferation and cytotoxicity (Gerlier and Thomasset, 1986). Antimicrobial susceptibility was tested on fungus (Saccharomyces cerevisiae), bacteria (Escherichia coli), and bacteria 93 94 (Staphylococcus aureus). KIRBY Bauer Disc Diffusion showed a Zone of Inhibition for these species (Indumathi et al. 2019). To measure film antimicrobial activity, overnight liquid cultures 95 96 of selected bacteria were diluted with 1 g L-1 peptone and 8.5g L-1 sodium chloride. UV light 97 sterilized 1.3 cm CS and Zr-CS-HAP film discs for 10 minutes. To each disk in a sterile tube, 98 200µl of liquid inoculum was added. The films were inoculated for 0, 2, 4, and 6 hours at 37 °C. Each tube was diluted with 1.8 mL peptone water (Tabassum et al. 2021). We cultivated 20 µl 99 100 aliquots of each diluted solution on Muller Hinton Agar at 37 °C before counting colonies. A triple statistical analysis was performed on each experiment (Raphael and Meimandipor, 2017). 101 Two samples of Zr-CS-HAP -2 and -3 were tested for antioxidant activity using DPPH free 102 radical scavenging (McDonald et al. 2006). Apoptosis, Necrosis, and other types of cell death 103 were characterised by the expression of phosphatidylserine on the cell surface, which is detected 104 by using Annexin-V as a probe (Homburg et al. 1995). Thus, viable, early apoptotic, late 105 106 apoptotic, and necrotic cells are represented by the populations Annex-V-/IP-, Annex-V+/IP, Annex-V+/IP+, and Annex-V-/IP+, respectively (Obrien and Bolton, 1995). Following staining, 107

109

propidium iodide is represented by the pink stain and Annexin V by the green stain. The yellow 108 tetrazolium dye MTT is reduced to formazan crystals by the MTT Assay test, which can be used

to measure cytotoxicity and cell proliferation. To evaluate viability, the MTT test (3-[4,5-110

dimethyl-2-thiazol]-2,5-diphenyl-2H-tetrazolium bromide) was employed. 111

112

113 **3 Results and discussion**

XRD can determine Zr-CS-HAP's crystal structure and microstructure orientation using the thin 114 film detector. XRD patterns show strong crystallinity, ZrO₂, HAP, and Chitosan peaks. Zr-CS-115 HAP diffraction peaks display the tetragonal phase of ZrO₂, coinciding with JCPDS card no. 89-116 7710, with a significant peak at 20 value 30.0°, corresponding to the (101) plane. HAP peaks at 117 20 values of 26.0° (002), 32.2° (211), 40.1° (310), and 45.9° (222) match the hexagonal 118 structure of hydroxy apatite and JCPDS card no 09-0432 (Ashkezari et al. 2023). Chitosan had 119 low peaks at 2 theta 15, 20.0°, and 36.7°, as before (R pallela et al. 2012). FTIR functional 120 groups of the composite film are presented in Figure 1. O-H stretching causes the spectrum's big 121 peak at 3385 cm-1. Chitosan amine peaks at 1629 cm-1 (Madeha and Ntanoyenkosi, 2024). 122 Peaks at 567, 1055, and 1566 cm-1 (phosphate groups) indicate HAP (Panda et al. 2003). 123 124 Spectrum data at 854, 1,413, and 1,451 cm-1 suggests carbonate ions. Also observed are Zr-O stretching peaks at 466 and 434. The spectrum shows all ZrO₂, Chitosan, and HAP peaks. A 125 Labsphere UV-2000F ultraviolet transmittance tester measured a few films' UPF (Balraj et al. 126 127 2017). Figure 1 depicts Zr-CS-HAP UV-visible diffuse reflectance spectra with various zirconia loadings. Figure shows absorption is concentrated at 308, 316, and 330 nm. Valence band to 128 conduction band transition may explain this. ZrO₂ nanosheets displayed no extrinsic states and a 129 high peak at 319 and 330 nm, according to literature. This suggested minor ZrO₂ nanosheet 130 surface defects (Fatemh and Mohammad, 2014). 131

132

Fig.6 UV-Vis DRS spectra, FTIR and XRD of Zr-CS-HAP thin films

133 134

A calibrated digital Vernier Calliper-gauge micrometer measures film thickness at five locations 135 for each film and calculates the average. Doping could alter film quality and microstructure. 136 137 Table 2 shows the weights of the films before and after 60 minutes in dry ethanol till saturated. SEM micrographs of zirconia loaded on HAP films at different magnifications are shown in 138 Figure 2. Figures (2a) and (2b) show just chitosan film, (2c) and (2d) show rod-shaped CS-HAP 139 films, and (2e) and (2f) exhibit Zr-CS-HAP films. Homogeneous films with considerable ZrO₂ 140

dispersion or nanofibers embedded in HAP films. SEM images reveal a film thickness of 14-49 µm. These values match vernier caliper measurements. Figure 3 illustrates EDAX pattern and metal % at a given time.

168 MTT Assay

Cytotoxicity should not be exhibited by biomaterials used in biological applications. Using an 169 170 MTT assay, Zr-CS-HAP thin films were examined in vitro to determine the nontoxic concentration. This MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyl tetrazolium bromide) assay, 171 measures mitochondrial activity by watching how cells transform MTT into formazan crystals 172 while they are still alive. The capacity of metabolically active cells to transform MTT into 173 formazan crystals was assessed. Based on the observations in Statistical data of cell cytotoxicity 174 study by MTT assay, it is suggesting that against HeLa cell lines, Test Compounds, namely Zr-175 CS-HAP-2 and Zr-CS-HAP-3 showing moderate cytotoxic potential properties with the IC₅₀ 176 Concentrations of 280µg/mL and 519µg/mL respectively. To demonstrate the mechanism of 177 action of films on human cervical cancer cells, more research was conducted, including 178 investigations on the cell cycle using PI staining, apoptosis using Annexin V/PI staining, 179 apoptotic protein expressions such as Caspase 3,7,9, Bcl2, p53, and ROS. 180

181

182

Fig.4 An EDAX Pattern of Zr-CS-HAP and a percentage of metal at a particular point

183 184 It is acknowledged in the literature that CS is nontoxic, and the incorporation of HAP induces 185 proliferative properties (Koopman *et al.* 1994). Moreover, the ZrO₂ was also reported to be 186 bioinert, and these coatings were expected to improve the interaction with cells and tissues. The 187 proliferation of the cells is due to the presence of calcium in hydroxyapatite. Calcium-sensing 188 receptors trigger chemotaxis and proliferation in response to elevated extracellular calcium 189 levels. In this regard, Zr-CS-HAP would be more beneficial because calcium can encourage 190 development and proliferation through the mechanical strength of Zr-based ceramics.

191

192 Anti-Microbial Susceptibility

193 The antibacterial activity of Zr-CS-HAP films was evaluated against three different 194 microbiological strains to see whether the powder's absorption into the film affected the behavior 195 of Zirconium and HAP. The disc diffusion method and viable cell count assay measured the 196 films' antibacterial and antifungal properties. The Zr-CS-HAP films repressed *Escherichia Coli* 197 Gram Negative, *Staphylococcus aureus* Gram Positive, and *Saccharomyces cerevisiae*. Table 3 198 lists the species and zone of inhibition. Films with less Zr-CS-HAP have smaller inhibition

zones. How well the inoculum kills germs depends on its concentration. Gram-positive bacteria 199 show no influence from Zr-HAP in the film (Figure 4a). Staphylococcus aureus may be resistant 200 to Chitosan films with a 1.5 log unit reduction. The regular Chitosan film and Zr-HAP film differ 201 202 slightly yet considerably. Figure 4b targets Gram-negative E. coli. Both examples had two log units fewer live bacteria after two hours with UV-absorbing powder in their matrix, proving that 203 the CS film is still effective against bacteria. A small shift occurred after 4 hours, and both 204 samples reached 5 log CFU/mL after 6 hours. As with other antibacterial coatings, a modest 205 uptick suggests weak microbial return. Although the bacterial population has grown, it is still 206 modest. A Saccharomyces cerevisiae test on the CS film showed just a slight decrease in active 207 microorganisms (Figure 4 c), ruling out considerable action. Live cells increased after 6 hours as 208 209 the Zr-CS-HAP film grew. Fungal activity-promoting compounds may be released during incubation. The elements may be organic bits or molecules. Although the chemicals have been 210 revealed in organism tests, the CS matrix's high antibacterial activity may have hidden their 211 benefits. But additional investigation is needed. Overall, Zr-CS-HAP films have outstanding 212 Gram-positive and Gram-negative antibacterial activity, peaking between 2 and 4 hours. Good 213 wound dressings, Zr-CS-HAP films absorb UV radiation and are antibacterial. 214

222 DPPH RSA

223 The CS-Zr-HAP films were studied for DPPH radical scavenging (RSA). The 2,2, diphenylpicrylhydrazyl (DPPH) technique has several medicinal and food-related uses. Antioxidant 224 activity of chemicals, especially phenolic compounds, can be evaluated using this approach. The 225 226 Spectrophotometer/ELISA reader's observations in the statistical results of the DPPH RSA study show that the test compounds Zr-CS-HAP-2 and Zr-CS-HAP-3, inhibited DPPH RSA in a dose-227 228 dependent manner with IC50 values of 663 µg/mL and 993µg/mL, respectively (Figure 5). The 229 standard control for the study was ascorbic acid. The measured DPPH radical scavenging conclusions of the tested compounds (Zr-CS-HAP-3) reveal that they have significant dose-230 dependent DPPH radical scavenging potency, while Zr-CS-HAP-2 and other samples have 231 232 moderate DPPH radical scavenging activity. Ascorbic acid & Zr-CS-HAP-2 both showed notable DPPH radical scavenging efficacy in a dose-dependent manner (Ngugen et al. 2022). 233

- 234

238 Apoptosis and necrosis

Annexin V/PI double labelling was used to quantify cell apoptosis and necrosis, and the results 239 are displayed in Fig. 5. When compared to the control group, the Zr-CS-HAP-2-treated cells 240 241 showed variable levels of necrosis instead of apoptosis. In late apoptosis or when the treatment period was prolonged, the necrosis rates of the Zr-CS-HAP-2-treated cells rose from 21.35% to 242 243 43.11%. (A) % live, apoptosis and necrotic population observed in HeLa cells treated with culture medium alone (Untreated), (B) Camptothecin and Test compound,(C) Zr-CS-HAP-244 2, with 72.83µg/mL concentration (D) Quadrant plots showing the % of HeLa cells that are 245 alive, in apoptosis, and necrotic after being subjected to the amounts of Camptothecin (3.8 246 µM/mL), Test compound, Zr-CS-HAP-2, and culture media alone (Untreated), respectively. 247 248

255

256

Zr-CS-HAP-2 with 72.83µg/mL	21.35	8.93	26.61	43.11

257

261

262 Conclusions

Chitosan, ZrO₂ HAP-based hybrid films were successfully prepared. The characteristics of these 263 films indicate that they are suitable for biomedical applications like wound dressings because 264 they help to reduce bacterial infections and bone tissue engineering applications. MTT assay, 265

The above graph and table clearly show that the study's Std control drug Camptothecin, the test 258 259 substance Zr-CS-HAP-2, significantly increased the amount of apoptosis (52%) and necrosis (21.35%) in HeLa cells. 260

266 DPPH, Apoptosis, and Necrosis studies also state that the Zr-CS-HAP-2 films have an impact

and possibility to explore in bone tissue engineering applications. Between two and four hours, the Zr-CS-HAP films exhibit the highest level of antibacterial activity against both Gram-

positive and Gram-negative pathogens. The fungal organism *Saccharomyces Cerevisiae* has been

- demonstrated to be mildly affected by Zr-CS-HAP film. Its bioactivity, biodegradability, and
- 271 biocompatibility make it highly beneficial in many scientific domains.
